

Colorimetric and Resolution requirements of cameras

Alan Roberts

ADDENDUM 24 : Menu settings for

Panasonic DVCPRO100 AJ-HPX2100

This document is a report of the results of tests that are the precursor of those described in the EBU technical document Tech3335. It is not an endorsement of the product.

A brief assessment was made on an engineering sample of the AJ-HPX2100 (serial number 3610365-0612-5, found in an unusual place), a multi-standard HDTV cam-corder with a Canon HA22x7 HD lens. It is very similar in form and function to the HDX900, sharing many features and having a very similar menu set. Production models may differ slightly from the pre-production model initially assessed for this addendum. No manual was available for these tests.

The camera is switchable between 1080-line and 720-line HDTV standards, and between the base-normal frame rates of 29.97 and 25Hz. It can also be switched, in 1080 mode, between interlace (50i, 59.94i) and progressive (25psf, 29.97psf, and 23.98psf in both 2:3 and 2:3:3:2 pull-down) modes. In 720P mode it can also be switched to half-frame rate, and thus can generate a “film look” in the camera at system speed. It has specific “film-look” gamma curves that incorporate many of the contrast handling features of earlier cameras, making it a great deal easier to set up. The camera has $3\frac{2}{3}$ ccds (1280x720, progressively scanned) and records at 100Mb/s (DVCPROHD intra-frame coding) onto P2 solid-state cards instead of the small-format conventional DVCPRO tape used in the HDX900.

It is a little larger than the HDX900, being wider to accommodate the P2 cards instead of the tape mechanism, and has HDSDI output. It has many internal menus for setting the performance, such that it can then be used without external controls. It is not ideally suited to multi-camera operation (being a camcorder) but has enough features to make multi use possible. Monitoring and connectivity have been improved over previous Panasonic models; it will genlock to either analogue HD Y or analogue composite (PAL or NTSC as appropriate); there are two video outputs, one switchable between HDSDI, SDI (appropriate down-conversion), and composite (PAL or NTSC), the other between HDSDI and HD analogue Y for monitoring; it has a IEEE1394 (Firewire) output that will feed and control an external recorder.

There is an 8-second video cache memory. Using this, it is possible to record up to 8 seconds of events that occurred before pressing “Record”. The same circuitry is also used to provide a “slow-shutter” in which adjacent frames are summed to produce smeared pictures and reduced noise (or extra gain).

Video compression is still DVCPROHD, 6.7:1 for all the NTSC-related standards, 6.3:1 for all the PAL-related standards. The camera section has 14-bit ADCs that deliver better noise performance than in earlier models. However, there are resolution issues that somewhat affect the usefulness of the camera in mixed format environments, it is not very good in SD, and is rather soft in HD.

In this setup, the gamma correction and knee are adjusted to capture about 2.5 stops of overload, and 1 stop of underexposure, to mimic film performance.

Since performing the test that form the basis for this report, Panasonic have announced a software upgrade that is claimed to improve the SD performance of the camera. Obviously, this upgrade has not been tested yet, such test would form the basis of a future revision of this document.

Colorimetric and Resolution requirements of cameras

Alan Roberts

ADDENDUM 24 : Menu settings for

Panasonic DVCPPro AJ-HPX2100

Many menu items have little or no effect on the image. Those that do so are highlighted. The full menus are given for completeness. Where two values are given {f} denotes film use, {v} video. The film mode uses the “Filmlike1” gamma curve, which very closely resembles the best that can be done with a conventional gamma curve and knee, but with a nice smooth join; there seems no point in ignoring this curve since Panasonic have clearly put much effort into its design, and it works well. The photographic speed of the camera is unchanged (about 640 ASA) using this curve (“Filmlike2” is a similar curve but copes with about a stop less of overload and reduces the photographic “speed” by about a stop, also the manual knee controls have no effect in this mode so it is not possible to customise it; “Filmlike3” further reduces the exposure range and lowers the photographic “speed” of the camera by about one stop more; both these modes should produce better noise performance and thus may well be the best option for film-like work). The video mode uses conventional gamma and knee settings to achieve similar results but with more contrast compression in highlights. Both modes can cope with about 2.5 stops of overexposure (about 500% measured); the video mode (with optimal knee settings) has a slightly more pronounced change of slope in the knee but the difference is marginal. Total exposure range has been measured as about 11 stops.

The shutter can be set to HALF (i.e. 180°), which avoids the problem of having to work out what it should be from the field/frame rate.

Line Mix mode (available as a User Switch setting) appears to be the equivalent of EVS in other cameras. Switched on in 25p mode reduces the vertical resolution to the same as 50i, thus minimising most interlace twitter artefacts although the effect is not great.

Digital Super Gain is implemented by reducing the frame rate. This gives “free” gain without noise, provided the smeared pictures and lowered frame rate is acceptable.

When shooting at 59.94 rates, drop-frame time code is always used.

Viewfinder and monitoring outputs can both have markers, individually set.

The camera “Gain” switch stores many camera settings, allowing the user to set completely different conditions selectable by that switch. However, most users will want only different gain, the menu contents given here are appropriate for the range of gains quoted, it is for the user to decide which gain settings are appropriate and to set the other conditions accordingly. Beware that the recommended settings were derived during a short laboratory test of the camera, better settings may well be found once the camera goes into general use.

Simply switching the camera into SD mode (but still using the HD lens), it produces significant aliasing artefacts, giving the picture an uneasy “business”, particularly in 576-line (625, “PAL”) mode. It is a little better in 480-line mode (525, NTSC), probably because the down-conversion algorithm is a simple one with insufficient filtering/interpolation. The effects are visible but subtle and may easily be mistaken for noise or compression artefacts, but were clearly visible on the SDI output. If the camera is to be used to make SD pictures, it is better to set the camera in HD mode and use an external broadcast grade down-converter, or to convert in software. Alternatively, using a SD lens would also reduce the aliasing. I have given evidence for this in the final section of this document.

Factory settings are underlined where known; since the tests were done without access to a manual for this camera, some descriptions are not complete. Menu items that differ from the HDX900, or are new in this model, are italicised; items that have only been moved are not so marked, menus are not all in the same order as in the HDX900. Settings for the HDX900 have the same effects in this camera.

This should not be used as a substitute for reading the manual.

1 Menus and settings

SYSTEM SETTING

System mode		Main video standard setting	
Item	Range	description	BBC
System Mode	1080-59.94i,1080-50i,720-50-59.94P,720-50P,480-59.94,576-50i	Any change requires a power-off/on cycle to take effect. Different defaults for E/P models	1080-50i
Rec Signal	Cam,1394,SDI	Picture source	
Camera Mode	50i,25p	N/A in 720p, contents change with Sys Mode	25p{f}, 50i{v}
VF Type	SD,HD

2 Measurement results

2.1 Colour performance

Assessments were made visually, using Macbeth charts as usual; performance was the same as for the HDX900.

2.2 Resolution

A HDTV zone plate chart was used (Fig.1). This contains six circular patterns that fully explore the spatial frequency performance of the camera, up to 1920x1080 pixels per width and height. In this illustration, there is serious aliasing caused by the scaling used to present it here.

2.2.1 Resolution at HDTV

Fig.2 shows a single quadrant of one pattern; for this exposure, the camera detail enhancement was turned off, so this is the native performance of the camera. There are clear null zones, where the wanted lower frequencies beat with the unwanted alias products, caused by the presence of higher frequencies, at 720 vertically and 1280 pixels horizontally. At first sight, this is to be expected from a camera using sensors of 1280x720 dimensions. However, it actually reveals that no tricks have been played in offset positioning of the sensors, precision horizontal offset of green from red and blue is a common trick to extend the resolution, and this can be done vertically as well. The resulting performance is a little disappointing. It is also evident that there is no optical spatial filtering in this camera, to suppress frequencies higher than can be resolved.

Judicious use of some detail enhancement (values are given in the tables above) improves the visual effect somewhat, but cannot produce resolution above the sensor limits of 1280 and 720.

On moving pictures, the aliases are visible as a disturbing “business” on sharp edges. It is easy to confuse these effects with the artefacts of video compression, but this test was done using the live HDSDI output; the DVCPProHD compression system can be expected to make the aliasing look worse.

Aliasing can cause difficulties in post-production operations where keying is used, since edges are not always where they are supposed to be.

2.2.2 Resolution at SDTV

When the camera is set to HD, but the digital output switched to SD, it should be able to deliver full SD resolution if used with a HD lens; Fig.3 shows the result, plotted with square pixels, again via SDI. This is the mode in which the camera is used to record HD, but monitoring is only SD, therefore it is important to see how well it works.

Since the card was framed to fill the picture, the scales still relate to HDTV pixel and line numbers. There is no clean resolution above about 452 lines vertically, nor above 720 pixels

Figure 1 zone plate chart

Figure 2 HD performance, detail off

Figure 3 camera HD, output SD, detail off

horizontally, but there is very visible aliasing around and above these limits. This is due to high frequency content of the HD image in the camera not being properly suppressed in the SD output; it indicates that the down-converter is poor, not using adequate (but expensive) filtering.

If the camera is to be used only to produce SD, it can be set into one of the SD resolutions. Fig.4 shows the result when set to 576i (“PAL”). Vertical resolution is improved, extending to 576 (the strict limit of resolution for SD) albeit together with aliased higher frequencies, but resolution near 576 is visible as inter-line twitter on an interlaced display, and is distracting. Unfortunately, aliasing around and above 576 is still present, again indicating that the down-converter is not properly suppressing these higher vertical frequencies.

Figure 4 camera SD 25p, detail off

Horizontally, the result is the same as for setting the camera to HD and monitoring in SD, which is no surprise.

Fig. 5 shows the result for setting the camera to 25p. Horizontally, there is no change. Vertically, the aliased frequencies above 576 are rather more visible, and there is a clear null zone (plain grey area) at 720, the vertical resolution of the sensors. This confirms that the high frequencies in the camera are not being suppressed properly in the down-conversion process. It also indicates that the lens is delivering more detail to the camera than it can resolve, even when in HD mode (since it cannot, in theory, resolve more than 720 vertically and 1280 horizontally), and this is evidence that there is no optical low-pass filtering in the camera.

When the camera is set to NTSC resolution, the vertical aliasing is rather less visible, but this is probably because the interline twitter from resolution around 480 lines/picture height dominates.

Figure 5 camera SD 50i, detail off

2.2.3 Detail enhancement at SD

So far, all the illustrations are without detail enhancement. The values given in the menu tables increase visible sharpness at HD, without causing excessive ringing, this is the same performance as in the HDX900. Fig.6 shows the effect of the same settings on the SD picture at 50i.

Sadly, the enhancement is mostly to the visibility of the aliased vertical frequencies above 452, and not to the wanted frequencies, with the maximum effect being highly visible around 720. Any attempt at sharpening the HD picture by using more detail enhancement will have the effect of exacerbating these aliased frequencies, both in the HD and SD outputs. Any degree of detail enhancement increases the visibility of interlace twitter.

These aliased frequencies occur in static pictures on scenes with high amplitude detail, and are disturbing once you know what to look for, but are immediately visible in most moving pictures, where they create a “business” on moving edges (because the aliased frequencies cause edges to move in the opposite direction to

Figure 6 camera SD 50i, detail on

the bulk of a moving object, creating a disturbing rippling effect on edges).

2.3 Conclusion

The camera produces spatial aliases from frequencies above 640 cycles/picture width (called 1280 pixels) and 360 cycles/picture height (called 720 lines). This shows that the HD lens delivers more resolution to the camera than it can resolve, and that there is no optical spatial filter in the camera. Also, the down-conversion in this camera is not very good, which is a shame. If the camera is to be used to make SD pictures for programme use, it makes no sense to use an HD lens, or even a best-quality SD lens. It is far better to use the camera in HD mode, and to use an external down-converter.
